## 1. OVERVIEW

### ***1.1. History of Mineral Exploration in James Bay (Eeyou Istchee)***

Mineral exploration in Eeyou Istchee has been the preoccupation (and occupation) of prospectors and mining companies for more than a century. The richness of the territory in terms of precious and base metals and recently in diamonds continues to increase yearly.

Historically, exploration has been mostly for precious and base metals, uranium and iron. Exploration intensity has always been influenced by the economic value of the minerals targeted. The Goldcorp Inc. Roberto mineralized system in the Opinaca Reservoir area (Wemindji-Eastmain section) has evolved as one of the most significant gold discoveries in Québec in recent years. The continuously positive exploration results obtained from this site prompt other companies to stake claims in the area.

Eeyou Istchee is gaining prominence as one of Canada's most important regions for mineral exploration. The Opinaca Reservoir has potential for being a major gold mining camp. The Otish Mountains area is very promising for possible diamond, gold, uranium and molybdenum exploitation. The Nemaska area has potential for lithium exploitation, the Mistissini and Waswanipi areas for gold and the Ouje-Bougoumou area for vanadium and iron.

### ***1.2. Geology of Eeyou Istchee***

James Bay Cree traplines mostly overlie the Superior geological province. A few Mistissini traplines are located on the Grenville geological province. The geology that follows is general in nature. The reader is invited to consult references listed or company websites for more comprehensive information.

The Superior Province forms the core of the continent of North America and represents the mining heartland of Canada. In Quebec, the Superior hosts the Abitibi, Matagami and Chibougamau mining camps. The Kapuskasing uplift represents a 500-kilometre-long fault-bounded structure that divides the Superior Province into western and eastern halves (Percival and West, 1994). The Superior Province is further divided into domains, subprovinces, terranes and complexes. This report follows nomenclature of tectonic elements put forth in reports by Hocq (1994) and Percival (2007).

Eeyou Istchee is located on the eastern Superior Province. Cree traplines overlies seven divisions of the Superior Province. These are from north to south:

- The Bienville Subprovince (Hocq and Percival)
- The La Grande Subprovince (Hocq and Percival)
- The Ashuanipi Complex (Percival) or Subprovince (Hocq)
- The Opinaca Subprovince (Hocq and Percival)
- The Nemiscau Subprovince (Hocq)
- The Opatica Subprovince (Hocq and Percival)
- The Abitibi Subprovince (Hocq) or Terrane (Percival)

These subprovinces are mostly made up of volcano-plutonic and sedimentary assemblages intruded by granitoids. They are transected by E-W to WNW-ESE and NE-SW-trending shear zones metamorphosed to (in the centre) the greenschist facies and (near their borders) to the upper amphibolite facies (Hocq, M., 1994).

The Bienville Subprovince (**on which the Whapmagoostui and Chisasibi communities and traplines are located**) is a plutonic assemblage occupying the southern part of the northern Superior province. It is composed mainly of migmatized orthogneiss ranging from tonalitic to granodioritic in composition, with enclaves of supracrustal (iron formation, paragneiss, metavolcanic rock) and plutonic (ultramafic) rocks intruded by synkinematic granodioritic to tonalitic plutons and by late biotite granites (Perreault and Moorehead, 2003). This subprovince also contains volcano-sedimentary belts, such as the Lac Fagnant Belt, metamorphosed to the amphibolite facies (Perreault and Moorehead, 2003). Plutonic rocks of the Bienville Subprovince intrude the northern margin of the La Grande Subprovince and mark a transition to dominantly granitic rocks to the north (Percival, 2007).

The La Grande Subprovince (**on which the Wemindji and Eastmain communities and traplines as well as some Chisasibi traplines are located**) is made up primarily of volcano-plutonic rocks and includes the La Grande Volcano-sedimentary Belt (LGVB). The LGVB runs parallel to the Wemindji-Caniapiscau structural Corridor. It consists of mafic to felsic volcanic rocks, interstratified with metasediments and oxide-facies or magnetite iron formations and hosts numerous known mineral occurrences. Scattered throughout the area are komatiitic flows and ultramafic intrusions which locally host Ni-Cu±PGE and Cr mineralization. In the west, the clastic Apple formation, which hosts uranium-gold occurrences, unconformably overlies Mesoarchean basement rocks (3.33-2.79 Ga) (Roscoe and Donaldson, 1988). The Venus belt in the northeast contains Ni-Cu-PGE showings (Gosselin and Simard, 2001). The Eastmain sector contains younger volcanic rocks (2.75-2.70 Ga) characterized by porphyry and other magmatic mineralization (Percival, 2007). The multiphase Meso to Neoproterozoic tonalitic basement associated to the Langelier Complex is overlain by autochthonous to para-autochthonous volcano-sedimentary sequences of the Yasinski Group and Ekomiak Formation.

The Ashuanipi Complex or Subprovince (**on which some Chisasibi and Mistissini traplines are located**) consists of high-grade metamorphic and plutonic rocks (Percival et al., 1992). Early sedimentary and volcanic rocks were intruded by a ca. 2.725 Ga tonalite-diorite suite (Percival et al., 2003), then deformed and metamorphosed to granulite facies and subsequently intruded by orthopyroxene-bearing diatexite (Percival, 1991), granite, granodiorite, and syenite (Leclair et al., 2004). Mineralization is restricted to small, high-grade gold showings in iron formation and skarns (Moritz and Chevé, 1992; Lapointe and Chown, 1993; Chevé and Brouillette, 1995). The occurrences are unusual in their setting in a granulite- facies terrane (Percival, 2007).

The Opinaca Subprovince (**on which some Mistissini and Wemindji traplines are located**) consists of metagreywacke, derived migmatite, and granite. Polydeformed schists occur at the belt margins, whereas the interior portions are metamorphosed to amphibolite and granulite facies (Percival, 2007). The northern boundary with the La Grande Subprovince is a faulted stratigraphic contact (Goutier et al., 2002). The supracrustal rocks are cut by the Broadback River granite (Davis et al., 1994). Mineralization in the Opinaca Subprovince includes rare-metal occurrences within peraluminous granites and associated pegmatites (Goutier et al., 2002).

The Nemiscau Subprovince (**on which the Waskaganish and Nemaska communities and traplines as well as some Eastmain traplines are located**) is made up mainly of metasedimentary rocks (Card and Ciesielski, 1986). The northern limit follows the contacts of the Lower Eastmain River volcanic belt (Franconi, 1978, Hocq, 1994). Hocq (1994) divides the Nemiscau Subprovince into the Champion Lake plutonic terrane and a metasedimentary terrane subdivided into three domains: the N-1 (northern part), N-2 (central part), and N-3 (southern part).

The Opatica Subprovince (**on which the Mistissini community and traplines as well as some Nemaska, Ouje-Bougoumou, Waskaganish and Waswanipi traplines are located**) is a predominantly metaplutonic domain adjacent to the northern boundary of the Abitibi Terrane and consists of units ranging from tonalite, through tonalite-granodiorite, to granite and pegmatite (Benn et al., 1992; Sawyer and Benn, 1993; Davis et al., 1994b). Polyphase deformation includes early, west-verging shear zones, overprinted by south-verging structures (Sawyer and Benn, 1993). The Frotet-Evans-Troilus greenstone Belt has showings including Cu-Au veins, volcanogenic massive sulphide, iron formation, and intrusion-hosted Ni-Cu (Gosselin, 1996). The Paleoproterozoic dolomitic Mistassini Group and clastic Otish Group of sedimentary rocks forming the Mistassini Basin and Otish Basin respectively unconformably overlie the Superior Province rocks.

The Abitibi Subprovince (**on which the Ouje-Bougoumou and Waswanipi communities and traplines are located**) is among the richest Archean greenstone belts in the world. It contains numerous granitoid intrusions and volcanic and sedimentary belts oriented roughly E-W. Volcanic units consist of ultramafic to mafic, mafic, or mafic to felsic assemblages. The volcanic assemblages are separated by narrow bands of sedimentary rocks generally composed of clastic

units. Several E-W to NW-SE oriented major reverse or normal faults, NE-trending sinistral faults and SE-trending dextral faults transect the Abitibi Belt.

In the James Bay region, strong positive magnetic anomalies are generally associated with iron formations (Houle, 2003). In these formations, disseminated sulphides may be detected from electromagnetic or induced polarization anomalies. In geochemistry, particularly in humus surveys, the most useful indicator elements for this type of mineralization are gold and arsenic (Houle, 2003). Houle states that fold hinges and transverse or longitudinal deformation zones affecting these iron formations are favourable sites for gold remobilization and local enrichment. Consequently, all iron formations located along the contact between major lithostratigraphic domains (sedimentary-volcanic) remain prime targets for the discovery of high-grade gold deposits.
